Abstract

The present communication deals with the observation and documentation on ethnomedicinal uses of wild plants by different socio-cultural groups of the south western part of Bengal. Information was recorded from interviewing different tribal healers by semi-structured open-ended questionnaire method. The vegetation index and location map were prepared by GIS technology. The collected data was analyzed by different statistical tools like Informant Consensus Factor (ICF), Fidelity Level (FL%), Use Value (UV), Consensus value for Plant Part (CPP), and Relative Frequency Citation (RFC). Total 119 numbers of species have been recorded which are used by tribal people for twelve large disease categories. Gastrointestinal (0.66) and respiratory (0.58) diseases are secure the highest ICF value. 84 species identified with 100% FL value and highest RFC value is recorded for *Calotropis gigantea* (L.) W.T Aiton and 55 species are noted as highest Use Value. This study enlightens the important species which is a primary step of any drug preparation.

Keywords: Ethnomedicine, NDVI, Quantitative tool, South west bengal, Tribes, Traditional knowledge

1. Introduction

‘Our country is a great Botanical garden of the world’, that gives us different herbal medicines from a very earlier time. There are approximately 47,513 numbers of plant species present in India (Singh and Dash, 2014). Among them, approximately 17,512 species are considered flowering plants (Karthikeyan, 2009) and according to the Botanical Survey of India about 8000 species are identified as medicinal plants. Medicinal plants play an important role in supporting the healthcare system from the very beginning (Van der Merwe *et al.*, 2001). The earlier “*Rig Veda*” (4500-600 B.C.) is the oldest repository of human knowledge regarding various herbal drugs. Indian eminent herbalist, 'Maharshi Charaka' worked on therapeutic uses of these different herbal drugs for different ailments of the human body. Later on, it is reported that

healers use near about 2500 plant species as regular sources of medicine (Sheng-Ji, 2001). Additionally, World Health Organization (WHO) has explained that 80% of the rural populations in developing countries utilize traditional medicinal plants for their health care. In recent times, some immemorial plants are invented for medicinal use by some traditional herbalists like 'Vaidya'. Medicinal plants have increased demand in the international market because they are cheap, easily available and no side effects. For that reason, some fraudulent businessmen can make their profits from the marketing of adulterated herbal drugs (Prakash *et al.*, 2013; Sagar, 2014). Throughout the previous century, allopathic treatments are used in India but if we consider remote areas of West Bengal most of the people are still now primarily dependent upon herbal

treatments. The recitation of previous literature it was found that documentation of ethnobotanical works has been done by different authors from these study areas (Ghosh, 2003, 2008; Datta *et al.*, 2014; Mandal *et al.*, 2014; Sannigrahi, 2014; Chaudhury *et al.*, 2018; Das Dutta and Bhakat, 2018; Manna and Mishra, 2018; Raj *et al.*, 2018). The quantitative study of ethnobotany is a new approach in this field to analyze the ethnobotanical data. Limited work with this approach was done in this region, where authors were mainly focused on particular community (Rahaman and Karmakar, 2015; Chaudhury *et al.*, 2017; Chaudhury *et al.*, 2018) and little international work was done (Chang *et al.*, 2017; Muhammad *et al.*, 2017; Faruque *et al.*, 2018). So, the exploration, documentation, utilization, restoration and conservation of these ethnobotanical resources are very much essential due to rapid civilization.

The present attempt was carried out in the south western part of West Bengal (Fig. 1) containing 5 districts viz. Purba Midnapore, Paschim Midnapore, Jhargram, Purulia and Bankura, in which Paschim Midnapore, Jhargram and Purulia districts are occupied by the maximum range of forest. The predominant species in this area is *Shorea robusta* Gaertn. The total area of Purulia district is about 6,259 sq. km out of this area 889 sq. km covered by forest. There are some scattered hills present in Purulia. Among them, Baghmundi and Ajodhya hill range are well known. The highest hill peak (677 meters from sea level) is present in Ajodhya, and it is the extension of the north-eastern part of the Chota Nagpur plateau. In the Baghmundi area, the average height of the hill is 300 meters and the hilly region is dissected by Kansaboti and Subamarekha Rivers. Here, the temperature falls in winter up to 7°C and rises to nearly about 45°C in summer. The annual rainfall is 1701 mm approximately. Due to this unique geographical territory, the selected areas have a high level of species richness.

Fig. 1. Location map of study area

In Paschim Medinipur district, there are four forest divisions. Medinipur Forest Division has 50267.49 ha. of area divided into nine territorial ranges. Jhargram Forest Division comprising of 621 Sq. km areas and it is one of the oldest forest divisions of south west bengal. Kharagpur Forest Division is primarily a social forestry division constituted in 1982 with a view of implementing a social forestry scheme project throughout the Midnapore district. Rupnarayan Planning and Survey Division since November 1995 emerged as a territorial division and it is also implementing different schemes related to soil conservation and social forestry works. The forest under each Division is managed with the active cooperation of the Forest Protection Committees. Reserved forest and open scrub are largest in Medinipur Forest Division while protected forest which constitutes the highest percentage of total forest areas in Jhargram Forest Division and the un-classed forest area is largest in Kharagpur Division. Extremely rugged topography is seen in the western part of the district and rolling topography is seen in lateritic covered areas. Normal rainfall in the district is around 1400 - 1500 mm. The average temperature of the district varies widely across seasons, varying between the maximum of 39°C and minimum 10°C.

The total area of Bankura district is 6881.24 sq. km and out of these, 1404 sq. km areas are covered by forest. Biharinath and Susunia are two remarkable hills in this district and the average height is 439.5 m above sea level. It is mainly situated on the northwestern side of this district. Maximum temperature varies between 26°C and 39°C. Winter is generally dry and cold with an average winter temperature around 15° C. The annual average rainfall ranges between 130 cm and 140 cm.

Distribution of Tribal communities: As per the 2001 census in West Bengal scheduled tribes numbering 4,406,794 persons constituted 5.5 percent of the total population of the state. Santal constitutes more than half (51.8%) of the total ST populations of the state. Oraons (14%), Mundas (7.8%), Bhumij (7.6%) and Kora (3.2%) are the other major ST communities having considerable population. The Lodhas, Mahalis, Bhutias, Bedias, and Savars are the remaining STs, and having population of one percent or more as per 2001 census report. The concentration index of tribal community is more than 1.50 in Purulia, Bankura, west Midnapur districts of south Bengal and low (less than 0.75) in east Midnapore (Mandal and Chouhan, 2018). As per the census (2011), among the total tribal people, 16.12% live in paschim Medinipur. These tribal communities mainly depend on the forest for food, fodder, economy, medicine etc. Herbal medicine uses are very much common among the tribes due to the lack of modern medical facilities or poor socio-economic conditions. In this region, each tribe has its own culture, customs, languages and beliefs.

2. Materials and methods

The study was conducted from 2017 to 2020. According to the standard method (Jain, 1987; Jain and Mudgal, 1999) the ethnomedicinal data were collected from different informants (Fig. 2) viz. *ojhas*, *vaidays*, herbal practioner, tribal people and local herbal drug sellers. Areas and informants were selected with the strong recommendation of aged persons of the respective villages based on the availability of traditional healers. Pre-informed open-ended personal interviews were organized to understand the uses of medicinal plants, the important parts of those plants, disease therapy, local name etc. All this information was documented and presented here. During the interview, visiting the forest or freshly collected plants had been employed for the initial identification of medicinal taxa. Furthermore, the selected medicinal plants were properly identified with the help of an expert and some flora books (Prain, 1903; Sanyal, 1994; *Flora of West Bengal*, no date). The collected information through various interviews was cross-verified for testing authenticity of the uses with the help of some available literature (Rahaman and Karmakar, 2015; Muhammad, Muhammad and Mehmood Abbasi, 2017; Chaudhury, Singh and Rahaman, 2018; Faruque *et al.*, 2018). Total 37 informants of the rural communities were interviewed randomly and only those informants were considered here, who responded independently without any influences. The interviews were taken in the local Bengali language and the nomenclature of identified specimens was authenticated with the help of World Flora Online (worldfloraonline.org) website. Mainly the herbaceous specimens were processed for herbarium through proper procedures (Jain and Rao, 1977) and the rest of them took photographs. The

Fig. 2. Some pictures of tribal informants at the time of interview. a. Gour Hansda, Gamghutu b. Jadupati Rajak, Hesadi c. Srikanta Tudu, Ramdongry d. Nigru Kalindi, Hesadi e. Bulu Kalindi, Hesadi

herbarium was deposited to Vidyasagar University Herbarium, Dept. of Botany and Forestry, Midnapore. At the end location of the study sites (Fig. 1) and forest areas (Fig. 3) of five districts (NDVI calculation for vegetation study) were prepared with the help of GPS data by ArcGIS software version 10.5.

Fig. 3. Vegetation map of selected five districts by NDVI method

2.1. Quantitative analysis

The collected data from the informants were analyzed with various quantitative tools like ICF (Trotter and Logan, 1986), FL (Friedman *et al.*, 1986), UVs (Phillips and Gentry, 1993), CPP (Monteiro *et al.*, 2006), RFC (Tardío and Pardo-de-Santayana, 2008) for understanding in details the diversity of uses plant parts, administration process in different communities. The significant methods used here for calculating the different quantitative indexes are describing below.

2.1.1. Informant Consensus Factors (ICF): One of the most widely used tools is the factor of informant consensus (ICF). This concept was first described by Trotter and Logan (1986) and its current form is proposed by Heinrich, *et al.* (1998 & 2009) after some modification. The ICF was calculated as the total number of use reports from informants for a particular disease category (*Nur*) minus the number of species used for that disease category (*Nt*), divided by the total number of use reports from informants for a particular disease category (*Nur*) minus one.

It is express by a formula: $ICF = \frac{Nur - Nt}{Nur - 1}$

2.1.2. The Fidelity Level (FL%): Fidelity level is proposed Friedman *et al.* (1986) and used to determine the percentage of informants who claiming the use of a certain plant for a particular disease. FL was defined as the ratio between the number of informants who independently suggested that the use of a species for a particular ailment and the total number of informants who mentioned that species are used for other ailments.

It is expressed by the formula: $FL = \frac{N_p}{N} \times 100$

Where N_p = number of informants who cited the species for a particular disease.

N = total number of informants that cited the species is used to treat any other disease.

2.1.2. Use Value (UVs): It measures the proportion of informants who consider a species as most important. This idea was proposed by Phillips and Gentry (1993 a, b) and Philips *et al.* (1994).

It is calculated by the formula: $UV_s = \frac{\sum U}{N}$

Where, U is the number of uses mentioned by the informants for a given species.

N is the total number of informants interviewed.

2.1.3. Consensus value for Plant Part (CPP): Consensus value for Plant Part (CPP) defines the most important plant part, that is used by informants much more than other parts of the plant (Monteiro *et al.*, 2006). It measures the percentage of agreement among informants who concerning the plant parts are used and is calculated as

$CPP = (P / Pt) \times 100$.

Where, P = number of times a given plant part was cited.

Pt = total number of citations of all parts.

2.1.4. Frequency of Citation (FC) and Relative Frequency of Citation (RFC):

The FC was calculated as follows:

$FC = (\text{Number of times a particular species was mentioned}) / (\text{total number of times that all species were mentioned}) \times 100$.

The RFC index (Tardío and Pardo-De-Santayana, 2008) was evaluated by dividing the number of informants who mentioned the use of the species (FC) by the total number of informants participating in the survey (N). The RFC index ranges from “0” when nobody referred to a plant as useful to “1” when all informants referred to a plant as useful.

$RFC = FC/N$.

3. Results and discussion

Demographic features of the informants: In our investigation, total 321 user reports were noted from 37 informants belonging to different socio-cultural groups like General, SC, OBC-B, ST, *Santal*, *Bhumij*, *Kurmi*, *Munda*, *Lodha*, *Dhopa* and *Teli*. All the informants are male and they were classified into different categories *viz.* informant types, professions, age, education, experience as given in Fig. 4. In this demographic feature, 1st category was set based on the type of informant *viz.* THP, IP. 23 numbers of THP and 14 numbers of IP were recorded out of total informants. The informants were farmers, *vaiddya*, tailors, plant sellers, and small businessman (Table 1) by profession. The 11 informants have primary school level education, 22 informants have secondary school level education and only 4 informants have high secondary education. Regarding age group, 30 or above 30 years old informants were independently participating in this program. The age of all informants was classified into 8 categories at ten years intervals. Category- 5 (61-70 years old) has the highest informant numbers (17). Besides that based on experience, informants were further classified into five categories on ten years interval, 15 or less than 15 years' experience (1st category), 16-25 years' experience (2nd category), 26-35 & 36-45 years' experience (3rd & 4th category). The last category (5th) possesses 10 informants having more than 45 years' of experience.

Fig. 4. Demographic information of all informants (THP- Traditional health practitioners, IP- Informative person)

3.1. Taxonomic classification

In the present work, I had found 119 species belong to 51 families and total 113 genera were documented which is used for the treatment of the different types of diseases in various tribal people. Most of the documented families belong to the angiosperm group but Pteridophyte and Gymnosperm represent only one species each. Out of the total angiosperm families, 4 families belong to

Monocotyledons and 45 families belong to Dicotyledons. Apocynaceae is represented as the most dominated plant family which possess 18 taxa, followed by Fabaceae (12 taxa), Euphorbiaceae (8 taxa), Combretaceae and Acanthaceae (5 taxa each), Asteraceae (4 taxa), Liliaceae, Malvaceae, Solanaceae, Verbenaceae, Rubiaceae (3 taxa each) and Amaranthaceae, Annonaceae, Nyctaginaceae, Menispermaceae, Amaryllidaceae, Convolvulaceae, Myrtaceae (2 taxa each), whereas other families were represented only one taxa (Fig. 5).

Fig. 5. Number of plant species in their representative family

It is also found that the maximum uses of medicinal plant species belonging to Apocynaceae and Fabaceae families for their wide range of distribution in this study area. The recorded species are categorized into four groups based on their habit viz. herb, shrub, climber and tree (Fig. 6). The herbaceous flora constitutes the highest contribution (35%), then tree (26.67%), a climber (20%) and shrub (18.33%) of the recorded plant species.

Fig. 6. Habit percentage of collected plants

3.2. Consensus value for Plant Part (CPP)

The various plant parts like root, leaf, fruit, flower, bark, even whole plant are frequently used for the treatment of diseases. Although all plant parts are significant for the treatment of different ailments in the

present investigation roots (24%) and leaves are maximum (22%) CPP value (Fig. 7). Apart from that, the uses of whole plant (14.1%), bark (11.2%), fruit (7.3%), seed (6.8%), latex, flower (4.5% each), stem (3.9%) and tuber or rhizome (0.56%). Different methods are applied for remedy preparation of different ailments by local healers viz. juice, paste and decoction. But the paste method was the most common for drug preparation because it is easy to make followed by decoction and juice (Fig. 8). The local informants were prepared a remedy not only by mixing different herbal ingredients but also some additives like turmeric, coconut oil, black salt, etc. The entire herbal ingredient was collected from the forest in the study area and non-herbal ingredients were collected from the commercial market.

Fig. 7. Contribution of plant parts for remedy preparation

Fig. 8. Contribution of plant parts for remedy preparation

3.3. Use Value (UVs)

The Use value (UVs) index is explaining the importance of plant species in a particular population for the treatment of a disease. In my investigation, the use-value of the reported plant species varied from 0.02-0.37. Based on UVs data, I had found eight plant species that have the highest UV value. These important medicinal plants are *Alstonia scholaris* [0.37] (Fig 9.a), *Justicia adhatoda* [0.32], *Calotropis gigantea*, *Strychnos-vomica* [0.30 for each], *Calotropis procera*, *Diospyros melanoxylon*, *Evolvulus alsinoides*, *Terminalia chebula* [0.27 for each]. These findings elucidated that, the extensive uses of the above-mentioned plant species by local healers for treatment of various diseases and it is also defined that these are the first choice of tribal healers to treat a disease. 34 numbers of plant species had been noted for the lowest UV value; it may be their abundance of low ethnobotanical uses.

3.4. Relative Frequency of Citation (RFC)

Frequency of citation (FC) indicates those plants that are mentioned many times by the informants out of the total numbers of times that all species were mentioned. In the present study, FC values varied from 0.31-4.98. The highest FC values are found on *Calotropis gigantea* (4.98), *Calotropis procera*, *Piper longum* [for each 3.11], *Gymnema sylvestre* [2.18]. Similarly relative frequency citation (RFC) values varied from 0.008-0.13. Among the total 119 species recorded, 86 species with RFC value equal to or higher than 0.016 are given in Table 4. The highest RFC value was recorded for *Calotropis gigantea* (0.13), *Calotropis procera*, *Piper longum* (for each 0.08), *Achyranthes aspera* [0.06]. The ethnomedicinal plant species having high RFC values indicated the abundant use and widespread knowledge among the tribal communities.

3.5. Fidelity Level (FL%)

The fidelity level of the recorded 119 important plant species ranged from 50-100% (Table 2). The high FL value of a particular species indicates the importance and considerable species for treating of his corresponding diseases. It may also be targeted, the investigation of bioactive compounds which are mainly responsible for the high healing potentiality of that species in my study area. 83 numbers of plant species have been noted with a high fidelity level (100%). These species are commonly growing in my selected areas but due to their high uses, it may be a chance of declining the population shortly.

3.6. Informant Consensus Factors (ICF)

To calculate the ICF, at first all the reported ailments were categorized into 12 different disease categories (Table 3). After that count the number of use reports (Nur) and the number of used taxa of each disease category (Nt). Now with the above mention formula, the ICF value (Table 4) was calculated. The ICF value of different disease categories was ranged from 0.66 to 0.28 and the average ICF value of all categories was 0.47. My study was revealed that there is a moderate ICF value among the informants regarding disease cure and medicinal plant uses. Gastrointestinal, respiratory, animal bite and neurological disorders secured the highest ICF value. This indicates that the medicines against these disease categories are very efficient and frequently used by the local healers. On the other side, among the four major disease categories gastrointestinal disorder was dominated with 203 number of use reports, followed by category others, pain and respiratory (86, 75 and 69 use reports, respectively). It is also found that the disease category gastrointestinal was used the highest percentage of plant species (57.98%) followed by category others, pain, ENEM, sexual disorder, respiratory, cardiovascular disorder, renal disorder, animal bites, parasitic disorder, neurological disorder and birth (38.65, 32.77, 32.77, 24.36, 21.84, 16.80, 15.96, 14.28, 10.92, 10.08 and 7.56, respectively). These findings also signify that gastrointestinal disorders are prevalent in the selected study area.

Thirty-one species are noted here for polyherbal remedy. Tribal people are used different plants for preparing remedies along with some supplements like resin of *Shorea robusta* (*dhuna*), sour yogurt, seeds of *Foeniculum vulgare* (*mouri*), seeds of *Nigella sativa* (*kalo jeera*), crystal sugar (*michri*), black cardamom, green cardamom, poppy seeds, ginger, *Sesamum* seeds, honey, rice water etc. Fabaceae is the most dominant plant family reported by (Rahaman and Karmakar, 2015; Chaudhury *et al.*, 2018; Manna and Mishra, 2018) in respect of ethnomedicinal uses by tribal practitioners. But from our investigation, it is noted that Apocynaceae is the most dominated plant family followed by Fabaceae (secure 2nd position), Euphorbiaceae (3rd position). In respect of habit structure of the used species by different socio-cultural groups, herbaceous species are found the maximum uses (35%) thereafter tree species. This habit ranking supports the previous work (Rahaman and Karmakar, 2015) from Bankura whereas (Manna and Mishra, 2018) shows that the tree species are the maximum uses species from the lalgarh forest range, Paschim Medinipur district.

Table 2. Different types of medicinal plant species are used by the Traditional healers of the study area

Sl. No	Scientific name of the plant	Local name	Family	Habitat *	Parts uses	Mode of uses*	Medicinal uses	NP	Major ailment	N	FC	RFC	FL %	UV
1	<i>Abutilon indicum</i> L. (Plate 1.a)	Potari	Malvaceae	S	Roots, leaves, seeds	D	Leaves are used in bronchitis, gonorrhea, inflammation of the bladder and fever. Table 3. List of ailments under broad disease categories

Sl. No.	Disease Category	Name of the disease
1.	Gastrointestinal disorder	Acidity, appetizing, bowel disease, carminative, cholera, constipation, diarrhoea, dyspepsia, dysentery, hepatic, hemorrhage, inflammation of bladder, jaundice, liver problem, piles, stomach disorder and ulcer.
2.	Respiratory disorder	Asthma, bronchitis, cough & cold, catarrhal pharyngitis, pneumonia and whooping cough.
3.	Poisonous bite	Snakebite and scorpion sting.
4.	Cardiovascular disorder	Anemia, cardiac, heart bit controlling, heart, hemoglobin enrichment, hypertension.
5.	Pain	Abdominal pain, arthritis, analgesic, chest pain, finger pain, gout, headache, rheumatic pain, stomach pain, tooth pain, throat pain and wound.
6.	Renal disorder	Diuretic, dysuria and urinal trouble.
7.	Sexual disorder	Aphrodisiac, gonorrhea, herpes, leucorrhea, menstrual and syphilis.
8.	Parasitic disorder	Anthelmintic, elephantiasis, malaria, scabies, vermifuge and worm.
9.	Birth related problems	Contraceptive, colic syndrome, pregnancy and milk production.
10.	Neurological disorder	Epilepsy, nervous weakness and paralysis.
11.	ENEM & skin	Leprosy, leucoderma, night blind, ophthalmic, scurvy, skin disease, tongue infection and teeth bleeding.
12.	Others	Astringent, beriberi, cancer, diabetes, dropsy, fracture, fever, leukemia, measles, pox, swelling, sleeplessness, spleen enlargement, tumor and vomiting.

Table 4. Informant consensus factor for each disease category

Category of Disease	Number of use report (Nur)	% of use report	Number of taxa used (Nt)	% of use taxa	ICF
Gastrointestinal	203	28.39	69	57.98	0.66
Respiratory	69	9.65	29	21.84	0.58
Poisonous bite	38	5.31	17	14.28	0.56
Neurological Disorder	23	3.21	12	10.08	0.50
Pain	75	10.48	39	32.77	0.48
Others	86	12.02	46	38.65	0.47
Sexual Disorder	53	7.41	29	24.36	0.46
Ear, Nose, Eyes, Mouth (ENEM) & Skin	72	10.06	39	32.77	0.46
Cardiovascular Disorder	35	4.89	20	16.8	0.44
Parasitic disorder	22	3.07	13	10.92	0.42
Birth related problems	13	1.81	9	7.56	0.33
Renal Disorder	26	3.63	19	15.96	0.28

Total one hundred and seventy-seven numbers of citations are noted on uses of plant parts. Different socio-cultural communities have mostly used the root of different medicinal plants and they are mostly preparing the remedy through the paste method which is supported by previous works in this region. The highest use values are noted on *Alstonia scholaris* (0.37), *Justicia adhatoda* (0.32), *Calotropis gigantea*, *Strychnos nux-vomica* (0.30 for each), *Calotropis procera*, *Diospyros melanoxylon*, *Evolvulus alsinoides*, *Terminalia chebula* (0.27 for each). It also gives an idea about which plants should be taken for detailed study in near future. This type of quantitative tool mainly attempted for assess the relative importance of species within the different socio-cultural groups, rather than only list-making exercise usually associated with most ethnobotanical studies (Datta et al., 2014; Mandal et al., 2014; Sannigrahi, 2014; Chaudhury et al., 2018; Das Dutta and Bhakat, 2018; Manna and Mishra, 2018; Raj et al., 2018).

Calotropis gigantea from the family Apocynaceae is the topper in the list of RFC rank. *Calotropis gigantea* commonly known as 'Akanda' has been identified for relief of any pain. Approximately 50% of informants have reported the uses of that species and out of 16 informants, 10 informants have claimed the uses of this species for any pain. Beside these uses, *Calotropis* sp. is prescribed for leucorrhoea, worm, rheumatic pain, elephantiasis, jaundice, epilepsy, scorpion sting, leprosy, teeth ache, asthma, bronchitis. Its uses were well confirmed as antimicrobial (Kumar et al., 2010), analgesic (Pathak and Argal, 2007), wound healing (Deshmukh et al., 2009), insecticidal (Alam et al., 2009), anti-diarrhoeal (Chitme et al., 2004), anti-inflammatory (Das et al., 2009), antioxidant (Singh et al., 2010), pregnancy (Srivastava et al., 2007). The RFC values emphasize the ethnobotanical data collected, based on popular species used by the different socio-cultural groups. It also gives an idea about which plants should be taken for detailed study in near future.

Besides Use Value, RFC value, Fidelity level (FL%) is another quantitative tool by which we can identify the species according to their relative effectiveness. It is also indicated the successful plant species for a specific disease in selected areas and utilization of that species by the local healers to treat any disease. Eighty-four numbers of species were found with 100% FL value. *Euphorbia fusiformis*, *Woodfordia fruticosa*, have also been reported for poor lactation, leucorrhea respectively (Chaudhury, Singh and Bharati, 2017) and *Syzygium cumini* for stomach ache (Rahaman and Karmakar, 2015) with 100% FL value. Informant consensus factors (ICF) ranged found in my study from

0.66-0.28 and the average value of all categories was 0.47 which was higher than the previous work (Muhammad, Muhammad and Mehmood Abbasi, 2017). The high ICF value indicates the species are used for particular disease categories is well known across the different socio-cultural groups. Whereas low ICF value indicates that either the knowledge regarding species is not transmitted among the different socio-cultural groups or it has been substituted by other species due to unavailability in their area. My findings signify that gastrointestinal and respiratory disorders are prevalent in my study region. Similar findings have been reported previously from Bangladesh (Faruque et al., 2018) and Pakistan (Muhammad, Muhammad and Mehmood Abbasi, 2017). Whereas different findings were also reported from China (Chang et al., 2017) and West Bengal, India (Rahaman and Karmakar, 2015).

In previous literature, *Abrus precatorius* (Fabaceae), *Aristolochia indica* (Aristolochiaceae), *Asparagus racemosus* (Aspragaceae), *Cissampelos pareir* (Menispermaceae), *Curculigo orchoides* (Hypoxidaceae), *Hemidesmus indicus* (Apocynaceae), *Rauvolfia serpentina* (Apocynaceae), *Woodfordia fruticosa* (Lythraceae) were reported for Leucorrhea and *Euphorbia fusiformis* (Euphorbiaceae) was reported as poor lactation by 'Lodha' tribe from Paschim Medinipur district, West Bengal (Chaudhury et al., 2017). In our investigation, the above mention species have different uses but *Aristolochia indica*, *Curculigo orchoides* also reported here for menstrual problem. *Woodfordia fruticosa*, *Euphorbia fusiformis* uses were found in this investigation for same purposes. *Aegle marmelos*, *Aristolochia indica*, *Asparagus racemosus*, *Cynanchum annularium* and *Mucuna pruriens* were reported for febrifuge (Dey and De, 2012) whereas *Aegle* sp. and *Aristolochia* sp. were also used here for febrifuge.

Ethno-medicinal uses of total 40 species were reported from Bankura Susunia hill on 'Santal' tribe (Rahaman and Karmakar, 2015), in which total 13 species are matched in my present investigation in respect of their uses. However *Diospyros melanoxylon* was reported as jaundice; *Oxalis corniculata* reported as gastric problem, stomachache; *Ricinus communis* reported as breast pain, scorpion sting, stomachache, induce lactation; *Tragia involucrata* reported as hair fall, scorpion sting but in my investigation, these species are mainly used for stomach disorder; scurvy; scorpion sting respectively. Ethnomedicinal documentation was done (Chaudhury et al., 2018) on 'Lodhas' tribal group of West Bengal and 250 ethnomedicinally important species were documented. From my investigation, it was observed that the uses of 21 species were partially matched and 29 species have other uses.

4. Conclusion

The study will enlighten the major phyto-resources used by tribal communities of the Western part of West Bengal. The quantitative tools are the very potent approach for the analysis of medicinal plants. With the help of quantitative tools, it was observed that *Calotropis gigantea* is highly potent plant taxa that have maximum uses in the selected area. Simultaneously few more species like *Woodfordia fruticosa*, *Euphorbia fusiformis*, *Alstonia scholaris*, *Aristolochia indica*, *Achyranthes aspera*, *Diospyros melanoxylon*, *Terminalia chebula* etc. also have tremendous medicinal uses. From this survey uses of seven species are recorded for new [*Anogeissus acuminata* (Roxb. ex DC.) Wall.; *Ceropegia candelabrum* L.; *Wattakka volubilis* (L.F.) Stapf.; *Cynanchum annalurum* (Roxb.) Liede&Khanum.; *Oxystelma esculentum* (L. f.) Sm.; *Pentatropis capensis* (L. fil.) Bullock.; *Utricularia bifida* Linn.] in these regions. It is found that many asclepiadaceae s.l. members are used for treatment of different ailments and one carnivorous plant also noted for treatment. The present survey is guiding us the potent medicinal plants for the study in future aspect and any application in drug preparation.

Acknowledgements

The study was supported by the Plant Taxonomy, Biosystematics and Molecular Taxonomy Laboratory, UGC-DRS-SAP & DBT-BOOST supported department, Department of Botany and Forestry, Vidyasagar University, Midnapore. We want to thanks Mr. Anup Kumar Bhunia and Mr. Dheeman Mondal, research scholar of my laboratory for their consistent helpful behavior. We are expressing our deep sense of gratitude Mr. Monaranjan Paramanik, Mr. Mahapada Hansda, Mr. Nandadulal Sanigrahi for helping us during the Purulia (Ajodhya) field survey. We want to express our gratitude to Miss Suparna Patra and her family for put together all the available tribal healers. We are also thankful to all the tribal villages for allowing us in their territory, peaceful co-operation and express their love & blessing. It is a very much memorable and valuable experience for us. Finally, we also thank to local communities and Panchayat for supporting us.
